## Abstract

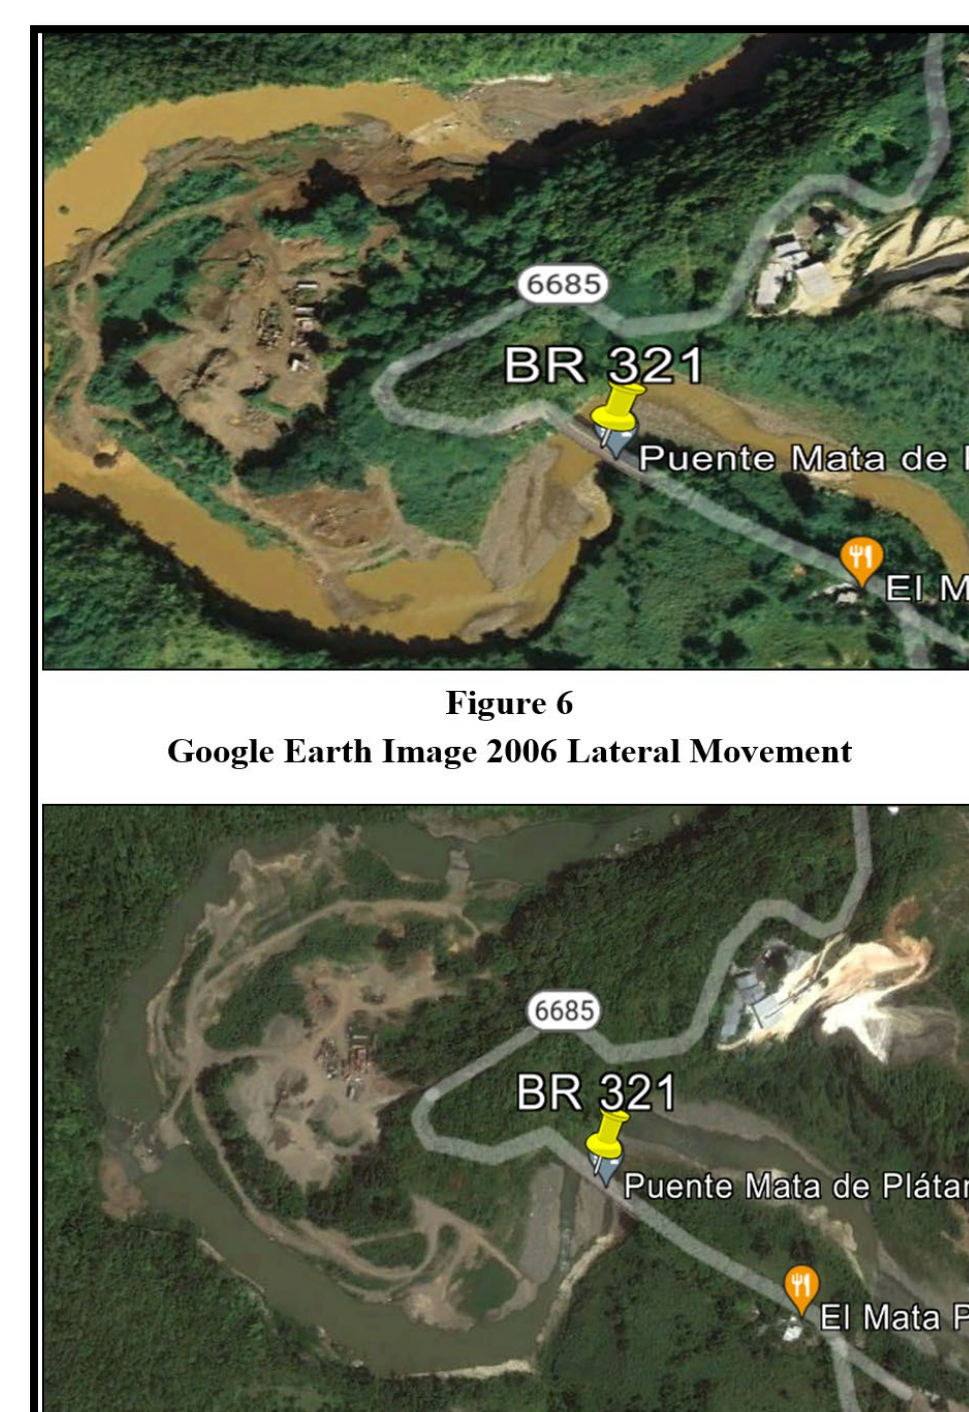

The scour on bridges is considered one of the main reasons for bridge failures. Scour is the consequence of the erosion action that is caused by the water flow. In pursuit of a possible direct relation to a water stream behavior a geomorphic analysis was conducted to a total of 26 bridges in Puerto Rico. A geomorphic analysis studies the plan and profile of a stream to understand the stream morphology of the river. The outcome will show if lateral or vertical movement has occurred on the river. After the analysis 88% of the bridges were meandering, 46% were classified as fair, 42% poor classification and only 12% were rated as good. The 46% lateral movement, 54% vertical movement, and none were stable.

## Introduction

Geomorphology is the study of landforms and the processes responsible for making and modifying the land throughout time. In Puerto Rico 26 bridges suffered from scour on piers and abutments. As a result of these findings a geomorphologic analysis was conducted on each of the bridges in pursuit of a relation of possible lateral or vertical movement on the water stream in order to prepare an efficient solution that considers the movement of a water stream prior to the construction of a bridge.

## Background

Active erosion on the riverbanks can occur at any time. Some water streams are more likely to erode than others. The erosion on the river banks could be for many reasons that involve landform, type of material on the riverbed, and mainly lateral and vertical movement of the water stream.

## Problem

The bridge scour in Puerto Rico is a main concern to maintain the safety of roads in compliance with the US Department of Transportation. The consequences of not preparing or mitigating against bridge scour could affect human life, the economy of a city or state, and damage the infrastructure of the roads downstream of a water stream when extreme events occur.

## Methodology

The geomorphic factors that affect stream stability consider 11 parameters. Those parameters will obtain a score, and finally the procedure will dictate if lateral or vertical movement occurred.

STREAM SIZE (Sect 2.3.2)	Small (< 30 m (100 ft.) wide)	Medium (30-150 m (100-500 ft.))	Wide (> 150 m (500 ft.))		
FLOW HABIT (Sect 2.3.3)	Ephemeral	(Intermittent)	Perennial but flashy	Perennial	
BED MATERIAL (Sect 2.3.4)	Silt-Clay	Silt	Sand	Gravel	Cobble or Boulder
VALLEY SETTING (Sect 2.3.5)	No valley alluvial fan	Low relief valley (< 30 m (100 ft.) deep)	Moderate relief (30-300 m (100-1000 ft.) deep)	High relief (> 300 m (1000 ft.) deep)	
FLOODPLAINS (Sect 2.3.6)	Little or none (< 2 x channel width)	Narrow (2-10 x channel width)	Wide (> 10 x channel width)		
NATURAL LEVEES (Sect 2.3.7)	Little or none	Mainly on concave	Well developed on both banks		
APPARENT INCISION (Sect 2.3.8)	Not incised	Probably incised			
CHANNEL BOUNDARIES (Sect 2.3.9)	Alluvial	Semi-alluvial	Non-alluvial		
TREE COVER ON BANKS (Sect 2.3.10)	< 50 percent of bankline	50-90 percent of bankline	> 90 percent of bankline		
SINUOSITY (Sect 2.3.10)	Straight (Sinuosity 1.1-1.05)	Sinuosity (1.06-1.25)	Meandering (1.25-2.0)	Highly Meandering (> 2.0)	
BRAIDED STREAMS (Sect 2.3.11)	Not braided (< 5 percent)	Locally braided (5-35 percent)	Generally braided (35-75 percent)		
ANABRANCHED STREAMS (Sect 2.3.12)	Not anabranching (< 5 percent)	Locally anabranching (5-35 percent)	Generally anabranching (> 35 percent)		
VARIABILITY OF WIDTH AND DEVELOPMENT OF BANKS (Sect 2.3.13)	Equiwidith	Wider at bends	Random variation		

Figure 2 Geomorphic Factors that Affect Stream Stability

Category	Score, R		
	Pool-Riffle, Plane-Bed, Dune-Ripple, and Engineered Channels	Cascade and Step-Pool Channels	Braided Channels
Excellent	R < 49	R < 41	N/A
Good	49 ≤ R < 85	41 ≤ R < 70	R < 94
Fair	85 ≤ R < 120	70 ≤ R < 98	94 ≤ R < 129
Poor	120 ≤ R	98 ≤ R	129 ≤ R

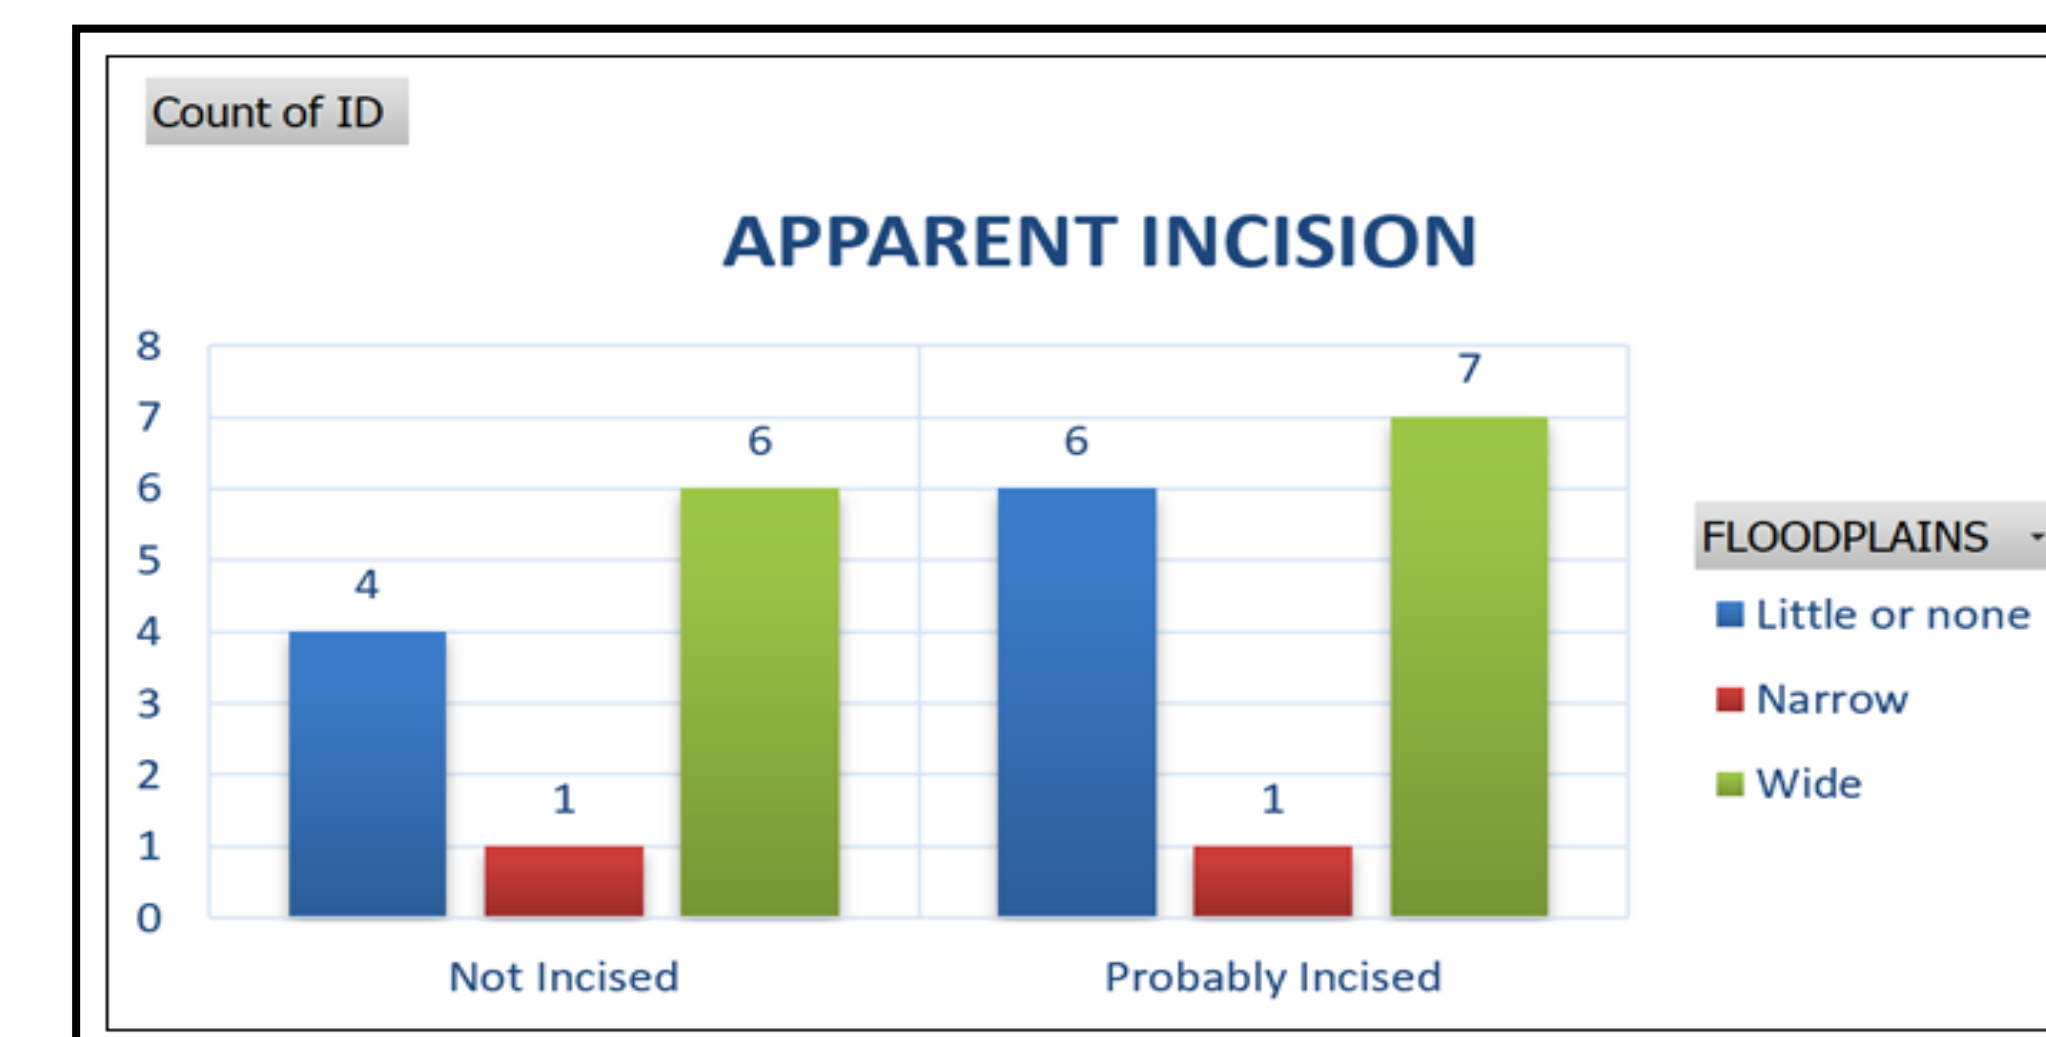

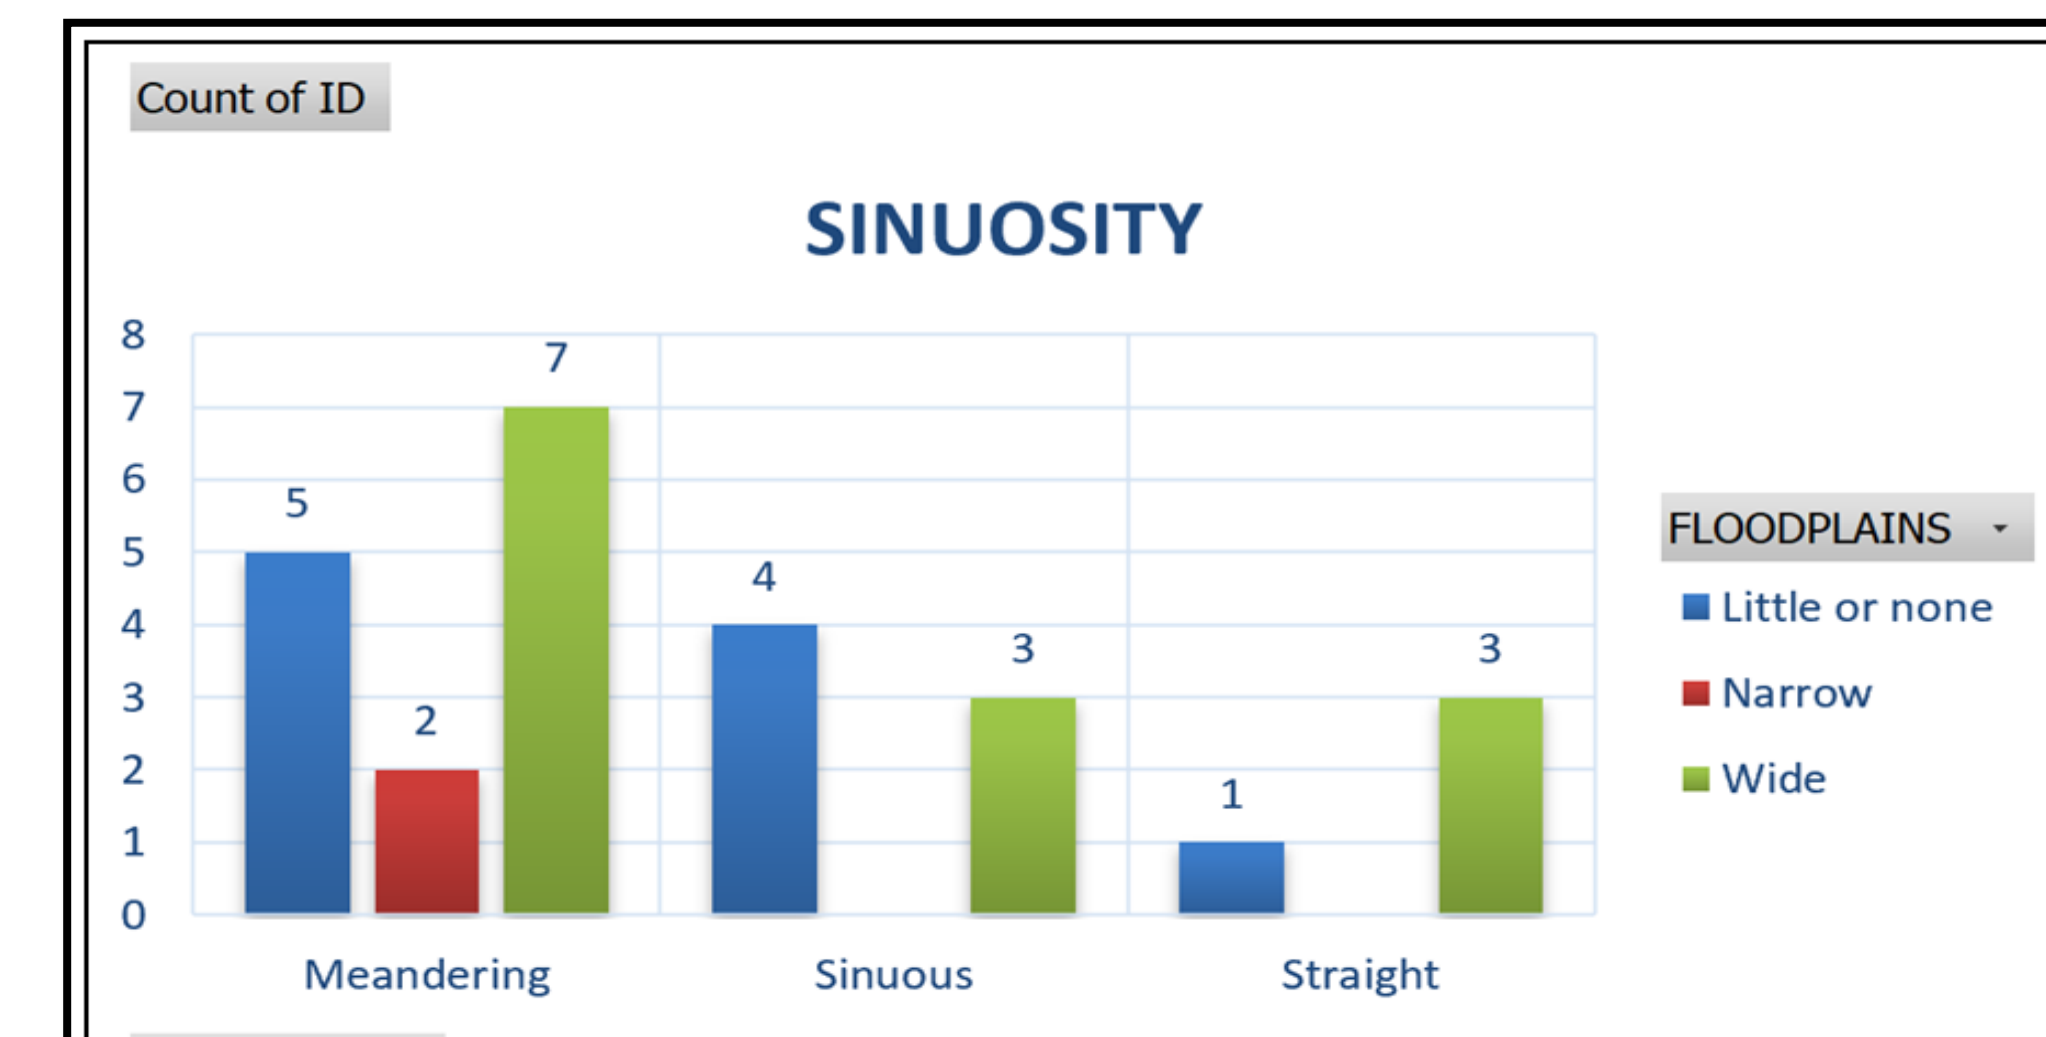

Stream	Indicator													Total	Rating Based on Table 5.5
	1	2	3	4	5	6	7	8	9	10	11	12	13		
Figure 5.11	12	4	6	12	11	10	10	12	12	11	12	12	3	127	Poor
Figure 5.12	9	12	10	7	11	8	3	11	8	10	6	7	8	110	Fair
Figure 5.13	8	2	4	5	3	5	5	8	5	2	2	2	6	57	Good
Figure 5.14	3	2	3	3	4	3	3	4	5	4	4	1	5	44	Excellent

Stream	Lateral	Vertical	Lateral Fraction	Vertical Fraction
Figure 5.11	62	33	0.86	0.92
Figure 5.12	50	26	0.69	0.72
Figure 5.13	25	13	0.35	0.36
Figure 5.14	23	10	0.32	0.28

Indicator									
Vertical Movement	Lateral Movement								
4	5	6	7	8	9	10	11	12	13

## Results and Discussion

The results obtained on the study showed that all of the bridges had lateral or vertical movement by conducting the geomorphic analysis. None out of the 26 bridges were classified as stable when a lateral or vertical movement analysis was conducted. These findings show a direct relation with the scour that occurred at these locations. The stability analysis, which is the second part of the geomorphic analysis, provides the result of lateral or vertical movement.

Parameter	Num. of Stream
Poor	11
Fair	12
Good	3
Excellent	0

Parameter	Num. of Stream
Lateral	12
Vertical	14

## Conclusions

The goal of the study was achieved by conducting a geomorphic analysis. The results found on the study showed that none of the bridges analyzed on the study were classified as stable. A stable classification states that there is no lateral or vertical movement on the water stream. Out of all the 26 bridges, 12 were classified as lateral movement, and 14 were classified as vertical movement. It is a priority to enforce on future proposed bridges to conduct a geomorphic analysis because it can provide quality information to analyze the site due to its landform, plan, material, sinuosity, and slope among other parameters.

## Future Work

The next steps to take into consideration are relating the geomorphic analysis with the location, water stream velocity, and site quarry because it promotes the incipient motion because the river stream always balances its course.

- Integrate GIS software as an important tool to determine landforms on river streams.
- Establish, implement, and maintain a process of a geomorphologic analysis for future proposed bridges.
- Evaluate bridges located on critical locations in order to determine lateral or vertical movement in order to prevent or mitigate future scour on bridge.

## Acknowledgements

Prof. Christian A. Villalta Calderón, Ph.D. deserves a lot of recognition and appreciation. Dr. Villalta was a big part of my mentoring and guiding me throughout this journey by sharing his passion and knowledge on water resources. Master Project classmates thank you for the support needed during this journey; it's been an honor. Finally, a special thanks to the Graduate School Staff for their professionalism and guidance during my Masters education.
